1	17.7.26	LEX Program TO Count lines, words, characters from given input		

Assignment - 1 24BCE2739 17/7/26

Write a LEX Program to count lines, words, and character from a given input

Concept used:

Lex is a tool to generate lexical analyser from a set of regular expression rules.

It scans the input character by character and matches patterns using regular expressions.

LEX uses pattern matching to count no of lines, words, characters. variables lines, words, chars are incremented based on matched patterns and `yystrlen` is used to determine length of each matched token.

Pseudo code:

1. initialise the counters
 lines = 0
 words = 0
 characters = 0
2. Read the input using LEX scanner (`yy lex()`)
3. for each matched pattern
 -> if newline (`\n`), increment line, and character counter
 -> if space or tabs, increment character counter
 -> if word is found, increment word length and add its length to the character counter
4. Continue scanning until end of input
5. Display total number of lines, words and characters
6. End Program

expected input:

first line

second line

third line

this is the first line

expected output:

lines: 4

words: 11

characters: 51
